Abstract. VIAP(Verifier for Integer Assignment Programs) is an automated system for verification of safety properties of a procedural program with integer assignments and loops. It translates a given program to a set of first-order axioms with quantification over natural numbers, and passes the resulting axioms, together with the given precondition and postcondition, to the SMT solver Z3. The system is fully automatic and points to a new way of proving properties of programs.

#### 1 Introduction

VIAP is a fully automatic program verifier designed for imperative programs proving the correctness of these programs with respect to a specification given as program assertions and assumptions. VIAP first translates the program to a set of first-order axioms with natural number quantifications using algorithm proposed by Lin [1]. It also tries to compute closed-form solutions of inductive definitions in Lin's translation using sympy [2]. The theorem proving part uses Z3[3] directly when the translated axioms have no inductive definitions. Otherwise, it tries a simple inductive proof using Z3[3] as the base theorem prover. VIAP can prove the (partial) correctness of the programs without needing loop invariants.

To illustrate how our system works, consider the simple program below:

```
int x = 1;
int y = 0;
while (y < 1000) {
    x = x + y;
    y = y + 1;
}</pre>
```

With some simple simplification, the translation outlined in [1] would generate the following axioms:

$$x_1 = x_3(N),$$
  
 $y_1 = y_3(N), \quad x_3(0) = 1, \quad x_3(n+1) = x_3(n) + y_3(n),$   
 $y_3(0) = 0, \quad y_3(n+1) = y_3(n) + 1,$   
 $\neg (y_3(N) \le 1000),$   
 $(n < N) \to (y_3(n) \le 1000),$ 

where  $x_1$  denotes the output value of the program variable x and  $x_3(n)$  a temporary function denoting the value of x after the nth iteration of the while loop. Similar conventions apply to y and its subscripted versions. The constant N is introduced to denote the number of iterations of the while loop before it exits. The variable n ranges over natural numbers and is universally quantified.

By using sympy our translator computes closed-form solutions for  $x_3()$  and  $x_3()$ , eliminates them, and produces the following axioms:

$$x_1 = (N * N - N + 2)/2, \quad y_1 = N,$$
  
 $\neg (N \le 1000),$   
 $(n < N) \to (n < 1000).$ 

With these set of axioms, Z3 can then be made to prove the assertion ((N\*N-N+2)/2) >= N at the end of the loop by constructing following z3 query.

```
x1=Int('x1')
N=Const('N',IntSort())
n=Int('n')
y1=Int('y1')
s.add(y1 == N)
s.add(x1 == ((-N + N*N + 2)/(2)))
s.add(main == 0)
s.add(N >= 1000)
s.add(ForAll([n],Implies(And(n < N,n>=0),n < 1000))))
s.add(Or(N==0,(N-1) < 1000))
s.add(N>=0)
s.add(Not((((-N + N*N + 2)/(2))>=N)))
```

Z3 returns with "unsat", thus proves that the axioms entails ((N\*N-N+2)/2) >= N.

#### 2 VIAP architecture

VIAP is implemented in python. The overall approach is illustrated in Figure 1. VIAP has been developed in a modular fashion and its architecture is layered in to two parts:

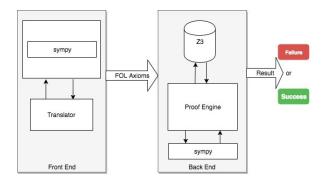

Fig. 1. Architecture Overview of VIAP

- Front-End: The system accepts a program written in C as input and translates it to first order axioms. Sympy solves the recurrences generated during the translation if closed form solutions are available.
- **Back-End:** Takes the set of translated first order axioms and translates all the axioms to Z3 compatible equation by pre-processing them using sympy. Then the proof engine applies different strategies and tries to prove post-conditions in Z3[4]).

#### 2.1 Proof Strategy

**Strategy 1: direct proof** In this Strategy, system attempts to prove assertions(s) from translated axioms, and assumption(s) by directly SMT solver Z3 [3] .

Strategy 2: Induction In this induction scheme, system attempt to prove any assertion of the form  $\beta(N)$  by proving  $\forall n.\beta(n)$  holds where n is the loop variable and N is the corresponding loop constant introduce by system. System adopt nested induction scheme to prove assertion(s) which involves two and more loop variables.

#### 3 Strength and Weaknesses

VIAP supports user assertions, including reachability of labels in the C-code. In SV-COMP 2018, these checks are only enabled for the ReachSafety category more specifically ReachSafety-Arrays, ReachSafety-Loops, ReachSafety-Recurrences sub-categories. However, VIAP provides little or no support for reasoning about dynamic linked data structures, bit-level precision, or programs with floating points.

Most formal verification tools for non-parallel imperative computer programs rely on having a suitable loop invariant to reason about the correctness of a given

loop. VIAP does not require loop-invariants to verify the correctness of programs. It does not produce a witness for a successful proof that the the program satisfies the stated assertions. This is because our system relies almost entirely on Z3 to prove the assertions. It does not attempt to compute or discover loop invariants; instead it translates programs to a set of inductive equations and first-order constraints about loops. Besides Z3, it only makes use of the algebraic system sympy for simplifying algebraic expressions and solving some simple recurrences. It also sometimes uses a simple mathematical induction on natural numbers. As far as we know, there is no simple solution to the problem of computing a "witness" when an automated theorem prover like Z3 claims that a proof is found.

### 4 Tool Setup and Configuration

The version of VIAP submitted to SV-COMP 2018 can be downloaded at: https://github.com/VerifierIntegerAssignment/VIAP-SVCOMP2018 VIAP is provided as a set of binaries and libraries for Linux x86-64 architecture. The options for running the tool are:

./viap\_tool.py [--spec=SPEC] INPUT

SPEC is the property file, and INPUT is a C file. If it terminates the output of VIAP is Result TRUE when the program is safe, Result FALSE, when a counterexample is found or Result UNKNOWN, otherwise. For each error-path , a file named <code>errorWitness.graphml</code> that contains the witness proof is generated in the VIAP root folder if it able to generate.

### 5 Software Project and Contributors

VIAP is an open-source project, mainly developed by Pritom Rajkhowa and Professor Fangzhen Lin of the Hong Kong University of Science and Technology. We are grateful to the developers of Z3 and sympy for making their systems available for open use.
